July 1982

INTRODUCTION

The Surveillance and Standards Section has the responsibility to plan and implement statewide monitoring programs of which long-term background water quality studies are an integral part. Data from such studies are used to evaluate the water quality of high priority stream reaches, e.g., those having domestic water supply and high quality coldwater fishery use designations, which might have existing water quality problems, or are expected to receive culturally induced stresses.

In the past century, several minor and one major mining operation occurred in the Upper Pecos River watershed. The most well known was the old Terrero copper mine on Willow Creek in the 1880's. Early finds of high-grade ores containing zinc and lead and subsequent discoveries of high grade gold and silver bearing ores in the early 1900's made the mine one of the better multiple producers in the country. Ore-body depletion and water intrusion were partially responsible for abandonment of the mine and closure of the mill, 12 miles to the south, in the late 1930's.

New reconnaissance techniques and a demand for metals have encouraged, in part, the present mineral exploration in the upper Pecos River watershed.

The Conoco Oil Mining Branch has been conducting deep exploratory drilling on the west side of the watershed near the abandoned low-producing Jones Mine (Figure 1) since the mid-1970's. The purpose of the reconnaissance survey was to define the location, size, and composition of a major ore body. Exploratory drilling was on a random pattern rather than the standard grid pattern since the ores occur in folded Precambrian granite. Sulfides of zinc, copper and lead with some gold and silver have been found in very high concentrations. No information is available though as to the type of mining proposed, the location of the mine, mill, and disposal sites, or if and when mining would take place.

The purpose of this EID-WPCB monitoring study was to characterize background water quality of the Pecos River and some of its major tributaries upstream from the town of Pecos prior to any potential major environmental disturbances, such as the development of a mining and milling industry. Maintenance of the upper Pecos River watershed in its present condition is of utmost concern because of its high recreational potential as a relatively unspoiled environment. Streams in this watershed are indicative of the highest category of protection (designated uses) afforded New Mexico streams by the Water Quality Control Commission as indicated in the "Water Quality Standards for Interstate and Intrastate Streams in New Mexico" WQCC 81-1; June 4, 1982).

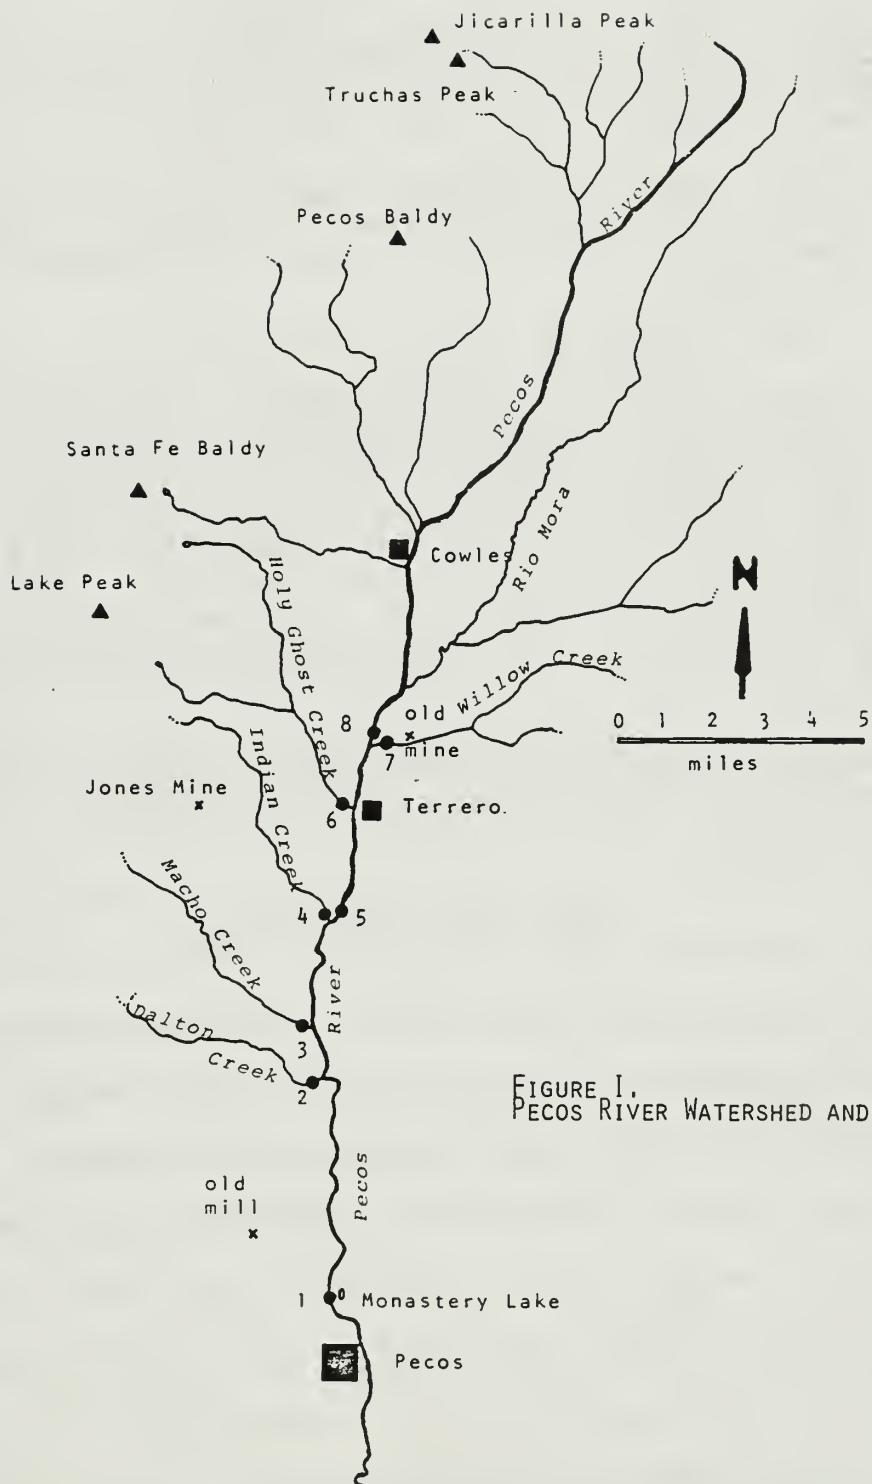

FIGURE I.  
PECOS RIVER WATERSHED AND SAMPLE SITES.

The designated uses and standards are:

Section 2-200. PECOS RIVER BASIN.

2-214. Cow Creek and all its tributaries and the main stem of the Pecos River from one mile below the Town of Pecos upstream to its headwaters, including all tributaries thereto.

A. Designated Uses: domestic water supply, fish culture, high quality coldwater fishery, irrigation, livestock and wildlife watering, and secondary contact recreation.

B. Standards:

1. In any single sample: un-ionized ammonia (as N) shall not exceed 0.02 mg/l; conductivity shall be less than 300  $\mu$ mhos; dissolved oxygen shall be greater than 6.0 mg/l or 85% of saturation, whichever is greater; total inorganic nitrogen (as N) shall be less than 1.0 mg/l; pH shall be within the range of 6.6 to 8.8; temperature shall be less than 20C (68F); total chlorine residual shall be less than 0.002 mg/l; total organic carbon shall be less than 7 mg/l; total phosphorus shall be less than 0.1 mg/l; and turbidity shall be less than 10 FTU.

2. The monthly logarithmic mean of fecal coliform bacteria shall be less than 100/100 ml, and no more than 10% of the samples shall exceed 200/100 ml.

#### STUDY AREA DESCRIPTION

The upper Pecos River watershed is in the Santa Fe National Forest in San Miguel County in north central New Mexico (Figure 1). The watershed lies essentially east of a major north-south fault. Headwater streams originate on the slopes of mountains which range in elevation from 12,500 to 13,000 ft. Western Santa Fe Baldy and Lake Peak are primarily composed of Precambrian granite while northern Pecos Baldy, Truchas Peak, and Jicarilla Peak are Precambrian quartzite. At upper elevations some Pleistocene glaciation occurred. The river beds in the study area are carboniferous sandstone and limestone and include boulders and smaller rocks comprised of

granite and some amphibolite washed down from higher elevations.

Precipitation amounts are as high as 30-35 inches per year, half coming during intense localized summer thunder storms at higher elevations. Up to 60 inches of snow can accumulate during winter months.

Pinon, juniper, and cottonwoods are the dominant forest vegetation at lower elevations but this changes gradually upstream to ponderosa pine, spruce, and fir with some cottonwoods along the stream course.

#### STUDY SITES

Water quality collection sites were established at six locations with perennial stream flows and two locations with ephemeral stream flows (Table 1, Figure 1). Sites were established to characterize Pecos River water quality: above and below the potential impact area - Nos. 1 and 8, respectively; above, within, and below impact areas on tributary streams - Nos. 2, 3, 4, and 6, respectively; within an old spoil-mining area - No. 7; and mid-watershed downstream from an old spoil mining area- No. 5.

Additional background water quality and quantity data are provided by a U.S. Geological Survey hydrologic bench-mark station established in 1962 at the mouth of Rio Mora Creek one and one-half miles above the study area and a USGS discharge gage located on the Pecos River near study site No. 5.

Table 1. Sample Sites in the Upper Pecos River Watershed.

| <u>No.</u> | <u>Location</u>                           | <u>Elevation</u> | <u>Flow</u> |
|------------|---|------------------|-------------|
| 1.         | Pecos River<br>at Monastery Lake          | 7000'            | perennial   |
| 2.         | Dalton Creek<br>upstream from Pecos River | 7240'            | ephemeral   |
| 3.         | Macho Creek<br>upstream from Pecos River  | 7360'            | ephemeral   |
| 4.         | Indian Creek<br>upstream from Pecos River | 7554'            | perennial   |
| 5.         | Pecos River<br>upstream from Indian Creek | 7554'            | perennial   |
| 6.         | Holy Ghost<br>upstream from Pecos River   | 7656'            | perennial   |
| 7.         | Willow Creek<br>upstream from Pecos River | 7800'            | perennial   |
| 8.         | Pecos River<br>upstream from Willow Creek | 7800'            | perennial   |

Also, a small water quality study was initiated by the Santa Fe National Forest Regional Office in the mid 1970's and the U.S. Geological Survey and Bureau of Mines recently completed a mineralization-water quality study of the upper watershed in the late 1970's (Harry Severtson, personal comm.).

#### METHODS AND MATERIALS

Three one-liter samples of water were collected at each site. One unpreserved and two preserved samples (one with 2 ml concentrated H<sub>2</sub>SO<sub>4</sub> and the other with 5 ml of concentrated HNO<sub>3</sub>) were stored on ice and sent to the New Mexico State Laboratory Division in Albuquerque for analysis of 29 water quality parameters. Basic water chemistry data were obtained on site (pH, temperature, and conductivity). A sample of water was fixed for dissolved oxygen analysis and percent dissolved oxygen concentration was calculated in the laboratory. All methods of collection and analysis followed procedures recommended by the USEPA (1979) and Standard Methods (APHA 1975).

Water samples were collected three to 10 times throughout the year commencing on October 30, 1980 and continued at approximately 6-week intervals until November 24, 1981. At some sites, one or two early sets of samples were analyzed for dissolved elements but analyses were later changed to total concentration. Measurements of total concentrations are consistent with the State's approach in establishing water quality standards.

Ten replicate samples of benthic macroinvertebrates were quantitatively collected at sites Nos. 1 and 8. These have not been

analyzed but should further document the high quality status given to the upper Pecos River watershed. A separate report should be completed in 1983.

#### RESULTS AND DISCUSSION

A cursory analysis of water quality data from all sites indicate these streams are cold, slightly alkaline and of medium hardness, with high dissolved oxygen and low amounts of total chemical constituents (Table 2). Water quality for most parameters was generally well below stream standards at all sites. Stream standards for total phosphorus were exceeded infrequently. Values greater than 0.1 mg/l for total phosphorus were observed on June 26, 1981 at all sites except Pecos River No. 5. Water temperatures on this date at all sites were also the highest recorded during the survey; up to 18°C at Indian Creek (No.4). Total phosphorus reached 0.13 mg/l in Macho Creek (No.3) on October 7, 1981.

Construction of a new road in the Indian Creek watershed and resulting erosion probably contributed to high values for total Kjeldahl nitrogen, total phosphorus, total non-filterable residue, calcium, and total bicarbonate at the Indian Creek site (No.4). High values for conductivity, total Kjeldahl nitrogen, nitrate and nitrite nitrogen, dissolved residue, calcium, and bicarbonate were present in Willow Creek (No.7) within the old Terrero mine site. Chemical dissolution and particle transport after soil and rock have been exposed may have contributed to elevated values (Buckman and Brady 1960; Hem 1970).

Water quality values for most heavy metals, e.g., arsenic, selenium, mercury, boron, cadmium, etc., were low or below the laboratory detection limit for the particular parameter. Total concentrations were well below values recommended for the protection of domestic water supplies and freshwater aquatic life (USEPA 1976; QCW and USEPA 1980; 45 FR, 79318).
